Liver diseases are a worldwide medical problem because the liver is the principal detoxifying organ and maintains metabolic homeostasis. The liver metabolizes various compounds that produce free radicals (FR). However, antioxidants scavenge FR and maintain the oxidative/antioxidative balance in the liver. When the liver oxidative/antioxidative balance is disrupted, the state is termed oxidative stress. Oxidative stress leads to deleterious processes in the liver and produces liver diseases. Therefore, restoring antioxidants is essential to maintain homeostasis. One method of restoring antioxidants is to consume natural compounds with antioxidant capacity. The objective of this review is to provide information pertaining to various antioxidants found in food that have demonstrated utility in improving liver diseases.

Key words: Antioxidant; Oxidative stress; Naringenin; Quercetin; Curcumin; Resveratrol; Silymarin; Coffee; Liver diseases

Core tip: The objective of this review is to provide an evidence-based update of antioxidants present in food and to describe their benefits on liver diseases.

INTRODUCTION

The liver is the main organ that metabolizes xenobiotics and endogenous molecules to maintain metabolic homeostasis in the organism. Therefore, the liver is a target of many insults that result in dysregulated hepatic homeostasis and lead to hepatic diseases. The liver is composed of the following cell types: hepatocytes, Kupffer cells, liver sinusoidal endothelial cells, pit cells, and hepatic stellate cells (HSC). Cirrhosis is caused by liver injury from a variety of etiological factors and is the end stage of progressive fibrosis. Oxidative stress plays an important role in the establishment of fibrosis and subsequently in cirrhosis. Therefore, the use of molecules with antioxidant properties has...
been proposed as a treatment for fibrosis and cirrhosis caused by oxidative stress.

**LIVER DISEASES**

Liver diseases are a major medical problem worldwide. There are numerous liver diseases caused by different insults, and the disease type depends on the location of development. The main causes of liver disease are viral and parasitic infections in regions such as Africa and Asia. Alcohol abuse is the most important cause of liver diseases in Europe and America. However, viral hepatitis has increased recently. Cirrhosis is likely the most important liver disease, and it is characterized by the accumulation of extracellular matrix proteins (including collagens I, III and IV) and distortion of the hepatic architecture.

**OXIDATIVE STRESS**

Oxidative stress is defined as an imbalance between the production of free radicals (FR) and the antioxidant defenses. The overproduction of pro-oxidants causes deleterious events in the cell such as lipid peroxidation, oxidative DNA damage, and protein damage. FR are defined as atoms or molecules with one or more unpaired electrons. FR can exist as radical cations or radical anions and are usually unstable and highly reactive because they can react with nearby molecules and abstract electrons. Oxygen can reduce and generate reactive oxygen species (ROS) by the interaction with transition metals or by the excitation of electrons secondary to the addition of energy. Oxidative stress contributes to fibrogenesis by increasing harmful cytokines such as transforming grown factor-β (TGF-β), interleukin-6 (IL-6), and tumor necrosis factor-α (TNF-α). Furthermore, TGF-β increases ROS production in endothelial cells, epithelial cells, smooth muscle cells, and fibroblasts.

**MAIN SOURCES OF FR IN BIOLOGICAL SYSTEMS**

There are several pathways to produce FR, the principal source in the body is own metabolism into the cell; however, this is not the only mechanism to induce oxidative stress. The environment plays an important role in the production of FR, ROS and reactive nitrogen species (RNS), for example, air pollution, UV irradiation, X-rays and gamma-rays. The production of ROS can be induced by endogenous or exogenous substances. The most important endogenous sources are cytochrome P450 metabolism, peroxisomes, microsomes, metal-catalyzed reactions, neutrophils, eosinophils and macrophages during inflammation, and mitochondria-catalyzed electron transport reactions in the complexes I and III. Ubisemiquinone has been proposed as the main reductant of oxygen in mitochondrial membranes, consequently, mitochondria generates approximately 2-3 nmol of superoxide/min per mg of protein, indicating that this organelle is the most important physiological producer of ROS and hydrogen peroxide (H₂O₂). However, there are other sources of superoxide anion (O²⁻) like xanthine oxidase, an enzyme that belongs to molybdenum iron-sulphur flavin hydroxylases, which is widely distributed among species and is present in several tissues in mammals. This enzyme plays an important role in the hydroxylation of purines, particularly, by the oxidation of hypoxanthine to xanthine, then from xanthine to uric acid. In both reactions, molecular oxygen is reduced, forming O₂⁻ in the first reaction and H₂O₂ in the second. Another endogenous source of ROS generation is during inflammation, by macrophages and neutrophils. Activated macrophages trigger an increase in oxygen uptake, resulting in the formation of O₂⁻, nitric oxide (NO) and H₂O₂. In neutrophils, nicotinamide adenine dinucleotide phosphate [NAD(P)H] oxidase generates O₂⁻ that is required for the respiratory burst necessary for bacterial destruction, also nonphagocytic NAD(P)H oxidases produce O₂⁻ in a range of 1%-10%. Cytochrome P450 enzymes are another pathway of ROS production during the breakdown or uncoupling of the P450 catalytic cycle. Microsomes generate 80% of the H₂O₂ at hyperoxia sites, and peroxisomes produce H₂O₂ but not O₂⁻ under physiological conditions, the liver is the major organ where peroxisomes contribute with the overall H₂O₂ production. Meanwhile, RNS like NO are synthetized by nitric oxide synthases (NOSs), which metabolizes arginine to citruline in a five-electron oxidative reaction, resulting in the formation of NO. Cells from the immune system can produce also NO in the oxidative burst triggered during inflammation processes. In the extracellular environment, NO can react with oxygen and water then to form nitrate and nitrite anions, also the NO and O₂⁻ can react together and lead to a more reactive FR called peroxynitrite anion (ONOO⁻) that can cause lipid peroxidation and DNA fragmentation.

**ANTIOXIDANTS**

Antioxidants are molecules that in low concentrations can prevent or delay the oxidation of an oxidizable substrate. Antioxidants are present in our body and exist in several foods. Antioxidants have a high affinity for FR and scavenge these molecules to protect our health. Compounds with antioxidant properties donate electrons to FR to reduce their reactivity and maintain the cellular pro-oxidant/antioxidant balance. There are many types of molecules with antioxidant activity. Natural compounds have been studied extensively and are relevant to many illnesses including liver diseases (Table 1).

**CURCUMIN**

Curcumin is also known as diferuloylmethane or 1,7-bis(4-hydroxy-3-methoxyphenyl)-1,6-hepadieno-
3,5-Dione. It is obtained from the rhizomes of Curcuma longa and has several pharmacological properties including strong antioxidant, anti-fibrogenic, anti-inflammatory, anti-microbial, and anti-carcinogenic actions in addition to wound healing effects [18,19]. Approximately, intake of turmeric in the Indian diet is of 2-2.5 g in a 60-kg individual, this is equal to 60-100 mg of curcumin daily. The Food and Drug Administration classified turmeric as a generally recognized as safe (GRAS). Toxicity assays on animals proved that curcumin is safe even at high doses. However, some species like mice and rats with prolonged high-dose intake of turmeric are susceptible to hepatotoxicity [20]. 3H-curcumin was found to be poorly absorbed in the rat intestine [21]. It is metabolized into curcumin glucuronide and curcumin sulfonate [22]. When curcumin is administrated intra-peritoneally, it is metabolized to tetrahydrocurcumin, hexahydrocurcumin and hexahydrocurcuminol [23]. Despite curcumin has low bioavailability when is administered orally, Arcaro et al. (2014) used piperine, an inhibitor of hepatic and intestinal concomitantly with curcumin. They had shown that both 90 mg/kg of curcumin and 20 mg/kg of piperine had antidiabetic and antioxidant effects. Nevertheless, coadministration of curcumin and piperine did not change the antidiabetic and antioxidant activity of curcumin. Additionally, when the dose of piperine was increased to 40 mg/kg this abrogated the beneficial effects of curcumin. Contrary, Sehgal et al. proved the effect of piperine in curcumin in mitigating benzo(a)pyrene toxicity in liver. They found that pretreatment of 100 mg/kg

</table>
of body weight of curcumin protects against a single dose of benzo(a)pyrene; however, the coadministration with piperine produced a better effect than curcumin alone, suggesting an enhancer activity by piperine. Curcumin has demonstrated hepatoprotective actions on acute and chronic liver injury[26]. Both of types of liver injuries necrosis, oxidative stress, and an inflammatory state[27]. In 2007, Reyes-Gordillo et al[28] demonstrated that curcumin inhibits the increase in cytokines such as TNF-α, IL-1β and IL-6. Additionally, curcumin reduces oxidative stress induced via carbon tetrachloride (CCl₄) metabolism by inactivating the nuclear factor-κB (NF-κB) pathway. Moreover, curcumin can elicit its hepatoprotective effect interacting with Fe²⁺ and Cu²⁺. In a study performed by Jiao et al[29], they suggest that curcumin could be an iron chelator because they found that transferrin receptor 1 and iron regulatory proteins, indicators of iron depletion, increased in response of curcumin. In agreement, Bernabé-Pineda et al[30], reported that when cyclic voltammograms are in basic media, that a chemical reaction has taken place between curcumin and specially Fe²⁺. On the other hand, curcumin has been tested in liver[31], but its chelating Cu²⁺ behavior has not been investigated; however, Baum et al[32] in 2004 tested the interaction of curcumin with Cu²⁺ and Fe³⁺, they reported that two molecules of curcumin bind to ion Cu²⁺ or Fe³⁺. In a study performed by Li et al[33], it was found that curcumin increases the levels of glutathione (GSH) and heme oxygenase-1 (HO-1), as well as, nuclear factor-erythroid 2-related factor 2 (Nrf2) proteins, suggesting another way to prevent oxidative stress by curcumin. In agreement, Charoensuk et al[34] have shown that curcumin increased the levels of mRNA and protein of Nrf2 and HO-1 and gene expression of NAD(P)H quinone oxidoreductase 1 (NQO1), glutamate cysteine ligase (GCL), activating transcription factor-3, peroxiredoxin 3 (Prdx3) and Prdx6, so increasing the antioxidant system in the cell. Curcumin also has demonstrated to increase the activity of superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx) and glutathione-S-transferase (GST) activity. Another mechanism of action of curcumin is by interacting with enzymes or genes implicated in liver cirrhosis. Hassan et al[35] proved effect of curcumin by modulating miRNA 199 and 200 that are the main miRNA associated to liver fibrosis. They showed that miRNA 199 and 200 were increased by the administration of CCl₄. However, curcumin restored these miRNAs to their basal levels. Finally, curcumin has shown that in low concentrations, it inhibits the activity of CYP2E1 and its protein levels in alcohol-induced liver damage, thus inhibiting the metabolism of alcohol for this pathway[36]. However, other studies have shown that curcumin does not have an effect on CYP2E1 activity in the liver[37,38].

RESVERATROL

The phytoalexin resveratrol (3,5,4'-trans-trihydr oxystilbene) is a polyphenol found in the skin of red grapes, red wine, peanuts and berries[42]. This compound possesses several beneficial activities including antioxidant, anti-inflammatory, anti-carcinogenic, and anti-fibrogenic properties, in addition to affecting lipid modulation[43]. The rate of absorption of resveratrol is approximately 75% after an oral administration[44]. Resveratrol is metabolized to resveratrol sulfate and in low concentrations to resveratrol glucuronide[45] via enzymes of phase II through UDP-glucuronosyltransferase (UGT) or sulfotransferase (ST)[46]. These results were based on in vitro experiments with hepatocytes treated with resveratrol. Conversely, in vivo experiments performed in rats demonstrated that the enterohepatic recirculation plays an important role in the overall systematic exposure to resveratrol when it was administered in aglycone or glucuronide form[47]. Resveratrol has been reported as a compound well tolerated in clinical trials[48]. Nevertheless, in a study performed by Crowell et al[49] in an animal model, resveratrol at the highest dose used (3000 mg/kg body weight/day for 4 wk) produced renal toxicity and reduced final body weights and food consumption as well as other markers of tissue lesions. However, no histological effects in the liver were observed, despite of the clinical chemistry changes and increased liver weight. On the other hand, Williams et al[50] reported not toxicity caused by high-purity transresveratrol at different times of exposure and doses. They used 700 mg/kg body weight/day for 90 d as the higher dose and time of exposure, not finding any adverse effect. In 2007, Chávez et al[51] demonstrated that resveratrol decreased the cytokine TGF-β and prevented hepatic fibrosis and NF-κB translocation to the nucleus following chronic use of CCl₄. Resveratrol has antioxidant capacity and protects against ethanol-induced lipid peroxidation[52], toxicity by acetaminophen (APAP)[53], and oxidative stress in animal models of cholestasis[54]. It has been suggested that the OH groups play an important role in the antioxidant activity of resveratrol[55]. A study performed by blocking OH group methylation showed that resveratrol and trimethylated resveratrol afford some degree of protection, but the latter possesses the best protective effects[54]. One explanation of this phenomenon considers that the half-life of resveratrol is very short[55] and that trimethylated resveratrol may act as a prodrug and increase the protective effect of resveratrol. However, resveratrol could be less potent than trimethylated resveratrol[56]. Another hepatoprotection mechanism of resveratrol is by activating genes related to antioxidant system or inhibiting enzymes. A study performed by Cheng et al[57] suggest that resveratrol can activate extracellular signal-regulated kinase (ERK) signaling pathway, which in turn can enhance the activation and translocation of Nrf2 to the nucleus, therefore, elevating the expression of HO-1 and glyoxalase. According to the previous study, Bagul et al[58] have shown that resveratrol was able to elevate the translocation of Nrf2 to the nucleus, thus suggesting an alternative pathway to protect from oxidative stress. Resveratrol has been reported to decrease acetylation
of peroxisome proliferator-activated receptor gamma coactivator 1-α (PGC1-α) and increasing its activity by the activation of the protein deacetylase sirtuin 1 (SIRT1), thus improving mitochondrial function and protecting against metabolic disease[58]. Price et al[59] found that resveratrol activates AMP-activated protein kinase (AMPK) in mice treated with moderate dosage and increase nicotinamide adenine dinucleotide (NAD⁺) levels, also increasing the levels of PGC1-α. AMPK has been shown to augment SIRT1 by increasing NAD⁺ levels in an indirect way, while this protein deacetylates the AMPK liver kinase B1, leading to phosphorylation and activation of AMPK. Zhu et al[60] have shown that, after administration of resveratrol in mice, the antioxidant system was increased (SOD, GPx, and GSH) in liver tissue as well as the levels of SIRT1 and p-AMPK were upregulated. Resveratrol has also shown to inhibit the activity of CYP2E1 in microsomes of rat liver[61], and to significantly inhibit the activity of this P450 isozyme in a model of APAP-induced liver injury[62] and in DEN-induced hepatocarcinogenesis model[63]. The only clinical double-blind study performed to determine the resveratrol hepatoprotective effect demonstrated that a 500 mg resveratrol dose for 12 wk caused a significant reduction in inflammatory cytokines, serum cytokerin-18, NF-κB activation, liver alanine aminotransferase (ALT), and hepatic steatosis grade compared to the placebo group in patients with non-alcoholic fatty liver disease (NAFLD)[64]. Contrary to this study, a clinical trial performed by Chachay et al[65] in 2014 showed that resveratrol did not significantly improve any characteristics of NAFLD compared to the placebo group. Interestingly, the results showed increased hepatic stress and elevated levels of ALT and aspartate aminotransferase (AST) in the liver. Based on these data, additional clinical trials are needed to determine the actual hepato protective effect of resveratrol[66].

COFFEE

Coffee is a mixture of several different molecules including carbohydrates, lipids, vitamins, alkaloids, nitrogenous molecules, and phenolic compounds[67]. Coffee is possibly the most popular drink worldwide[68]. However, the amount of antioxidants in different bean roasts can vary[69]. The three major compounds present in coffee are caffeine, diterpene alcohols (cafeolol and kahweol), and chlorogenic acid[70]. Coffee consumption has been associated with the reduction of several chronic diseases[71]. This result may be due to the pharmacological properties that have anti-necrotic, anti-fibrotic, anti-cholestatic, chemoprotective, and antioxidant functions[72]. Caffeine is the best-known active component of coffee, and it is absorbed rapidly after an oral ingestion (5 min) and reaches its peak blood levels after 30 min. When caffeine is consumed in high amounts produced side effects. Recommendations from Health Canada in 2013, stipulated that the caffeine intake per day for children should not exceed 2.5 mg/kg of body weight. Additionally, tachycardia and arrhythmia typically arise when more than 200 mg of caffeine are ingested[73]. Worthley et al[74] have given 250 mL of a sugar-free energy drink to 50 young people, this drink contained about 80 mg of caffeine, they have observed that caffeine increased the blood pressure compared with controls. Moreover, other kind of sickness have been reported for caffeine consumption such as cardiovascular diseases, a negatively impact in cognition, perpetual memory and learning[75]. Smith et al[76] in 2002, reported that the intake of 300 mg of caffeine increased anxiety and tension. Also, caffeine triggered hallucinatory experiences in people who drink 300 mg of coffee (about 7 cups per day). Patients with panic disorders were more sensitive to caffeine[77]. The half-life of caffeine is approximately 5–6 h[76,77]. Caffeine is almost completely metabolized in the liver. The principal metabolite is paraxanthine, which results from the activity of CYP1A2. However, this enzyme produces other metabolites such as theobromine, theophylline, and 1,3,7-trimethyluric acid. Other enzymes such as CYPs 1A1 and 2E1 participate in caffeine metabolism[78].

An important property of caffeine is that it easily passes through the blood–brain barrier[79]. The absorption rate of chlorogenic acid is 33% of the dose in both, rats and humans. Several metabolites have been identified in human plasma and urine, and these metabolites include polyphenolic acids, glucose conjugates, sulfates and glucuronides of hydroxycinnamic acid, and hydrogenated hydroxycinnamic acid[80]. Many studies have shown an inverse relationship among coffee consumption and liver cirrhosis[81]. In the prospective study performed by Klatsky et al[82], the authors demonstrated an inverse coffee-cirrhosis relationship for the first time. In 1994, Corrao et al[83] performed a study and identified a dose-response relationship between coffee intake and cirrhosis. The data show that the odds ratio for liver cirrhosis decreases from 1.0 for people who do not drink coffee to 0.47, 0.23, 0.21, and 0.16 for 1, 2, 3 or 4 cups of coffee daily, respectively. Furthermore, the study showed that the caffeine per se did not show any relationship with cirrhosis by testing other drinks with caffeine. Although coffee is beneficial to liver health, the study failed to demonstrate a causative role of coffee in preventing liver injury. Thus, additional basic research and controlled prospective studies are needed. Arauz et al[84] in 2013 demonstrated that coffee has a beneficial effect on liver injury caused by chronic administration of thioacetamide (TAA). Caffeine prevented cholestasis and necrosis measured by the enzymes γ-glutamyl transpeptidase (γ-GTP), alkaline phosphatase, and ALT. Human trials demonstrated the same results[85]. This inverse relationship was particularly high in heavy alcohol drinkers[86]. Conversely, liver injury inhibits caffeine metabolism, and people with liver diseases may experience adverse consequences after drinking coffee. Furthermore, it is important to distinguish between former coffee drinkers and nondrinkers in future epidemiological studies[71,85]. Moreno et al[87] in 2011 and
Arauz et al.\textsuperscript{[72]} in 2013 demonstrated in murine models that coffee prevents experimental liver cirrhosis in two models of liver injury using carbon tetrachloride and thioacetamide. Both studies showed that coffee reduces the expression of the profibrogenic cytokine TGF-\( \beta \). The study by Arauz et al.\textsuperscript{[72]} measured the expression of connective tissue growth factor (CTGF), which has been suggested as an important downstream modulator of TGF-\( \beta \) that increases its profibrogenic response. This finding is consistent with the significant upregulation of extracellular matrix in fibrotic liver\textsuperscript{[126]}. Cavín et al.\textsuperscript{[84]} have reported coffee as an inductor of GST, aldo-keto reductase, GSH, HO-1, glutathione-S-transferase P1, which are enzymes involved in the detoxification process. Also, they suggest that a possible mechanism of chemoprotection of coffee is by stimulation of Nrf2 pathway. In another study, coffee was able to elevate mRNA levels of NQO1 and glutathione-S-transferase A1 in liver and small intestine also, UDP-glucuronosyltransferase 1A6 and GCL catalytic (GCLC) were increased in small intestine. Further, the same group reported that this induction was bigger in mice possessing Nrf2 in contrast with Nrf2 knockout mice\textsuperscript{[80]}.

**QUERCETIN**

Quercetin is also known as 3,3',4',5,7-penta-hydroxyflavone. It is a flavonol found in natural products, especially in apples and onions\textsuperscript{[90]}. Quercetin is known to have biological effects including chelation of heavy metals, anti-carcinogenic, cardioprotective, bacteriostatic, anti-inflammatory, and antioxidant properties\textsuperscript{[90]}, in addition to functioning as a hepatoprotective agent\textsuperscript{[91]}. The normal intake of quercetin is less than 5-40 mg/d. However, people who eat the peel of food with high amounts of quercetin may consume 200-500 mg/d\textsuperscript{[90]}. In 2004, high purity quercetin used in foods was GRAS measured by HPLC in rat liver microsomes\textsuperscript{[94-97]}. In 2013 demonstrated in murine models of liver injury using carbon tetrachloride and thioacetamide. Both studies showed that coffee reduces the expression of the profibrogenic cytokine TGF-\( \beta \). The study by Arauz et al.\textsuperscript{[72]} measured the expression of connective tissue growth factor (CTGF), which has been suggested as an important downstream modulator of TGF-\( \beta \) that increases its profibrogenic response. This finding is consistent with the significant upregulation of extracellular matrix in fibrotic liver\textsuperscript{[126]}. Cavín et al.\textsuperscript{[84]} have reported coffee as an inductor of GST, aldo-keto reductase, GSH, HO-1, glutathione-S-transferase P1, which are enzymes involved in the detoxification process. Also, they suggest that a possible mechanism of chemoprotection of coffee is by stimulation of Nrf2 pathway. In another study, coffee was able to elevate mRNA levels of NQO1 and glutathione-S-transferase A1 in liver and small intestine also, UDP-glucuronosyltransferase 1A6 and GCL catalytic (GCLC) were increased in small intestine. SILYMARIN

Silymarin is a natural substance derived from Silybum marianum, also known as Milk thistle or Saint Mary's thistle[5]. Silymarin has been reported as a safe compound in acute doses in animal models due to its lack of side effects. In contrast, in a clinical trial, thousands of patients suffered mainly mild gastrointestinal disorders by silymarin consumption[107]. In other clinical trial, El-Kamary et al[108] (2009) no side effects were reported in 105 patients using 140 mg of silymarin. The range of doses used in literature is from 280 to 800 mg/kg of body weight/day. After oral administration, the silymarin peak plasma concentration is reached at approximately 6-8 h. Silymarin has poor bioavailability (23%-47%). The metabolites of silymarin are conjugated in the liver by UGT and ST (phase II reactions)[109]. Among the hepatoprotective effects of silymarin, it is known that silybin, the major constituent of silymarin, has iron-chelating properties[110,111]. Silymarin has also been probed as iron chelator in children with β-thalassemia with iron overload[112]. In a study performed by Najazdeh et al[113], they suggest that hepatoprotective effect of silymarin in iron-overload induced hepatotoxicity was due to an iron-chelator activity but no studies have been made proving the chelating properties per se of silymarin in liver diseases. Silymarin has hepatoprotective properties against several hepatotoxins such as CCl4. Silymarin can prevent oxidative stress, fibrosis, cirrhosis, and lipid peroxidation by modulating the content of phosphatidylethanolamine[114]. Thus, it improves liver enzyme activities and protects against the harmful increases in cholesterol/phospholipids and sphingomyelin/phosphatidylcholine ratios in the membrane. This effect was associated with a decrease in Na+/K+ and Ca2+-ATPase activities induced by CCl4. However, silymarin does not reverse well-established cirrhosis[115-119]. Kim et al[120] showed that silymarin increases nuclear translocation of Nrf2 in activated HSC, however, expression of other molecules related to a detoxifying effect have not been measured. Also, silymarin has been reported to increase the activity of antioxidant enzymes like SOD, GPx[121] and CAT[122]. A clinical trial examining silymarin in a complex with phosphatidylcholine found reduced levels of the liver enzymes, ALT and γ-GTP, and serum bilirubin levels in a dose-dependent manner in patients with hepatitis caused by virus infection or alcohol abuse[123]. Another clinical study showed similar results when silymarin was administered alone[124]. In patients with cirrhosis, silymarin administration for 41 mo significantly increased the survival rate compared to a placebo group[125]. However, in the study performed by Parés et al[126], silymarin showed no effect on survival rate in the clinical course in alcoholic patients with liver cirrhosis.

NARINGENIN

Naringenin is also known as 5,7,4'-thihydroxyflavonone. Naringenin is a flavanone found in citrus fruits and tomatoes[127]. In a study performed recently, Yang et al[128] reported that naringenin does not cause deleterious effects in beagle dogs, the maximum time of exposure was 180 d and with doses varying of 20, 100, or 500 mg/kg body weight/day. Also, Surampalli et al[129] showed that naringenin was harmless upon exposure to rat gastrointestinal epithelium in doses ranging from 1 mmol/L to 100 mmol/L, thus suggesting naringenin as a safe compound. Naringenin has many pharmacological properties including hypolipidemic, anti-hypertensive, anti-inflammatory, antioxidant and anti-fibrotic functions[127]. Flavonoids are absorbed in the aglycone form rather than in the glycoside form like quercetin. The glycoside form of naringenin is cleaved in the small intestine before absorption, which results in sulfate and glucuronide metabolites in the small intestine wall and liver[127,130] by UGT and ST. Mira et al[131] showed that naringenin has shown capacity of reduction of the Fe3+ and Cu2+ in less potential than quercetin. Chtourou et al[131] found that naringenin prevents the depletion of SOD, CAT, GPx and GSH. Conversely, naringenin also prevented the increase in lipid peroxidation, ALT and AST. Additionally, expression of the following genes was also affected in an NALFD rat model induced by a high cholesterol diet: pro-inflammatory cytokines TNF-α, IL-6, and IL-1β, EGF-like module-containing mucin-like hormone receptor-like 1, iNOS, NF-κB, MMP2 and MMP9[131]. Similar results were obtained by Yen et al[132] using naringenin-alone and a naringenin-loaded nanoparticlesystem (NARN). Both treatments exhibited antioxidant and hepatoprotective activities. The treatments also inhibited the activation of caspases 3, and 8. However, NARN was more effective as a hepatoprotector and antioxidant than free naringenin because it also inhibits caspase 9 during CCl4-induced hepatotoxicity in rats[132]. In a study performed by Goldwasser et al[133], it was found that naringenin activates peroxisome proliferator-activated receptor alpha (PPARα), then decreasing the levels of very low density lipoprotein production without causing lipid accumulation in hepatocytes, in a hepatitis C virus (HCV) model. Similar results were found by Cho et al[134], who have shown that naringenin intake causes a significant depletion in the amount of total triglycerides and cholesterol in plasma and liver of rats. Also, naringenin-fed animals showed an increment in PPARα protein expression in liver. Goldwasser et al[133] found that the flavonoid regulates the activity of PPARγ and liver X receptor alpha (LXRA), by activating the ligand-binding domain of PPARα and PPARγ, while inhibiting LXRA, thus modulating different genes related to fatty acid oxidation and lipogenesis. Han et al[135], found that a pretreatment with naringenin-7-O-glucoside increased NQO1, ERK and phosphorylation and translocation of Nrf2 to the nucleus in H9c2 cardiomyocytes, as well as, upregulating the
mRNA expression of GCLC and GCL modifier[135], thus inducting endogenous antioxidant enzymes. Similar findings was reported by Esmaeili et al[136], they showed that naringenin was capable of attenuating CCl4-induced liver injury by downregulating TNF-α, iNOS and cyclo-oxygenase-2, both protein and mRNA, as well as by increasing Nrf2 and HO-1 expression. Motawi et al[137] suggested that naringenin could be another example of CYP2E1 inhibitor, they probed it, in rat liver microsomal assay in co-administration with simvastatin, and such inhibition of CYP2E1 is another via to improve antioxidant defenses[137]. There are currently no studies available in human hepatic disorders[138].

GREEN TEA

Camellia sinensis, also known as green tea, is a worldwide consumed beverage. Its beneficial effects on health are due in part to its antioxidant, anti-inflammatory, anti-arthritic and anti-angiogenic effects. Moreover, green tea is a mixture of polyphenols (the major class of active compounds) including catechins (also known as flavan-3-ols) which constitute about 30% (mass fraction) of green tea leaves; the major catechins in green tea are (−)-catechin, (−)-epicatechin, (−)-epigallocatechin, (−)-epicatechin-3-gallate, (−)-gallocatechin, (−)-gallocatechin gallate and (−)-epigallocatechin-3-gallate (EGCG). Flavonoids like quercetin, kaempferol and myricetin; methylxanthine alkaloids such as caffeine, theophylline and theobromine, and phenolic acids (gallic acid, chlorogenic acid and caffeic acid)[139,140]. EGCG is the most abundant catechin and represents up to 50% of total polyphenols and possesses the strongest antioxidant capacity, therefore, it is considered the main biological active compound[141]. On the other hand, green tea does not only exert its antioxidant properties by polyphenols, L-theanine is the primary amino acid in green tea and represents 1%-2% of the leaf dry weight, it is synthetized in the roots of green tea and is concentrated in the leaves. L-theanine chemical structure is similar to glutamic acid, the latest is a precursor of GSH. Studies have shown that L-theanine protects the cell maintaining the levels of GSH in cancer and neurotixicity diseases[142]. The intake of green tea can be considered safe when its consumption does not exceed 1-2 cups/d. Nevertheless, hepatotoxicity has been attributed to the intake of green tea when it is used for weight control; furthermore[140]. Pérez-Vargas et al[141] found that L-theanine prevented the increased expression of NF-κB and down-regulated IL-1β and IL-6 and the cytokines TGF-β and CTGF induced by carbon tetrachloride. Moreover, the expression of the corresponding mRNAs decreased accordingly. On the other hand, L-theanine promoted the expression of IL-10 and the fibrolytic enzyme metalloproteinase 13 (MMP13). In a study performed by Yu et al[142] they have shown that EGCG ameliorates liver inflammation, necrosis and fibrosis and suppressed the expression of TNF-α, IL-1β, TGF-β1, MMP9, α-SMA, and Col-1α1. Similar results were obtained in HSC cell line LX-2, where EGCG was capable of suppressing TGF-β1, Col-1α1, MMP2, MMP9, TIMP1, and α-SMA. Moreover, Bin Dajem et al[143] used the aqueous extract of green tea in a Schistosoma mansoni-infected mice model to investigate its effect on the oxidative stress, antioxidant system and liver pathology induced by the parasite. They found that green tea extract suppressed the oxidative stress by decreasing the lipid peroxides. However, failed to enhance the antioxidant system and to reverse alterations in the liver such as necrosis. In a study performed by Higashi et al[144] they found that EGCG modulates the growth of HSC activated cells by Rho-signaling pathways and induces the phosphorylation of ERK 1/2, c-Jun kinase and p38, suggesting a mechanism of its anti-fibrotic capacity. In a cisplatin-induced nephrotoxicity model in rats, EGCG increased the levels of Nfr2, HO-1, SOD, CAT, GPx and GSH[145]. In clinical trials, green tea has shown protective effects against various kinds of cancers, including premalignant prostate, esophageal, colon, rectum and pancreatic cancers[146]. Nevertheless, in hepatocellular carcinoma, green tea did not have any protective effect[147]. In a study performed by Halegoua-De Marzio et al[148] they have shown, after a single oral dose of green tea (400 mg), in patients with cirrhosis induced by HCV, that it is safe and well tolerable by all patients, therefore suggesting the use of green tea in the treatment of cirrhosis in the future. However, more clinical studies related to the beneficial effects on liver diseases are needed.

The information shown above represents some of the antioxidants uses in different kind of experiments in animals and clinical trials. However, it is difficult to say which of these antioxidants possess the best hepatoprotective properties since they have different chemical structures and antioxidant potency, then its scavenger capacity is not the same. Moreover, other parameters need to be considered, such as the bioavailability, and pharmacokinetics. We focus our hepatoprotective ranking mainly based on the chemical structure showed in Figure 1. We suggest that silymarin has the best hepatoprotective effect because it is a mixture of flavonolignans including silybin, isosilybin, silydianin, silychristin, isosilychristin and the flavonoid taxifolin. In addition, silybin is composed of 2 diasteroismeric compounds (silybin A and silybin B) in a 1:1 ratio[149]. Flavonoids in its structure have different forms to stabilize FR including hydroxyl phenolic groups, double bonds and sometimes a catechol group[90]. Therefore, silymarin seems to be the best choice referred to hepatoprotective effect. Green tea is another mixture of polyphenols, as mentioned earlier, containing catechins, flavonoids and methylxanthine alkaloids. Nevertheless its data referred to hepatoprotection is lower than silymarin, for these reason we decided ranked green tea in the second place. The antioxidant property of EGCG is related of its hydroxyl phenolic groups, that maybe acts mainly from hydrogen atoms transfer or single electron transfer reactions. This groups are presented in the B- and D-rings of...
Quercetin, as mentioned above, is a flavonoid that have all the elements to exert a magnificent hepatoprotective effect related to its structure showing a catechol group in the B ring, substitution of hydroxyl phenolic groups in the A and C ring and a double bond in the position 2-3 of the C ring. Curcumin has been used in the treatment of experimental liver diseases since 1970 and shows a powerful antioxidant capacity and immunomodulatory properties. However, it does not have the same structure of flavonoids, showing two hydroxyl phenolic groups and a heptadiene linkage two methoxyphenol rings. Ak et al. suggest that keto form of curcumin, the heptadienone linkage between the two methoxyphenol rings, contain a carbon atom that can donate a hydrogen, therefore, stabilizing FR. We considered that its capacity of stabilize FR is lower than quercetin. Resveratrol possesses hydroxyl phenolic groups and a system of conjugated double bonds that can donate electrons to FR. Resveratrol has two phenolic rings: monophenol and diphenol. Gülçin suggests that subtraction of hydrogen atom is easily in the monofenol ring. Naringenin is another flavonoid with lower antioxidant capacity than quercetin, shows a hydroxyl phenolic group in its structure in the A ring. However, it does not have the catechol group or the double bond.

Also, Cao et al. suggest that in flavonoids the hydroxyl substitution is relevant in the ORAC activity. Caffeine has double bonds in its structure. Chu et al. reported that pure caffeine had very low ORAC values, whereas, crude caffeine had higher values than pure caffeine. We considered that caffeine has the lowest antioxidant activity of all the compounds showed; therefore coffee has the lowest antioxidant capacity.

**CONCLUSION**

Investigations of antioxidants show that compounds in food are candidates for the treatment of several diseases because they improve the antioxidant system in the body, especially when the disease involves oxidative stress. This review describes antioxidants that can be investigated for experimental and clinical trials and will be used for the treatment of liver diseases such as liver cirrhosis. Curcumin, quercetin, and naringenin are effective in the treatment of experimental liver injury, and they can be studied in clinical trials. Green tea have been shown to protect against different kinds of cancer in clinical trials, except in hepatocellular carcinoma. Conversely, there are no clinical trials investigating resveratrol, coffee, and silymarin. However, the data are poor or contradictory, and it is necessary to perform more clinical trials to use these antioxidants for the treatment of liver diseases such as liver cirrhosis.
treatment of liver diseases in patients.
